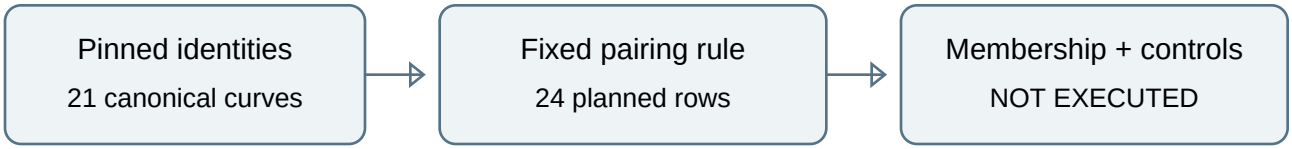
Fixed-x test: source and protocol validation

27 October 2026 | Source-only record | GOAL-NISTSEED-ab8949 remains unresolved

No new study memberships have been evaluated. This report records a prospective exact checker and its static validation. It is not approval, a run result, a historical reconstruction or an independent review.

Prospective workflow - no new membership outcomes



Planned test

Hold the next published Gx fixed across the earlier named qualifying candidates in the same timestamp stream. Retain 11 canonical omissions, 10 published self checks and 3 distinct P-224 opposite-sign sensitivities. The 24 rows are correlated. Repeat as deterministic A/A and retain planted positive, negative, zero-boundary, source-corruption and circularity controls.

Static observations

The exact four-file Coordinator delivery was preserved. Original source hash and Python syntax passed. The repository protocol validator found two enum errors; both failures remain visible. Coordinator-approved pre-freeze corrections preserve all planned rows and use exact committed-byte admission for bound files while recording unrelated dirty paths. The corrected draft passes the actual protocol validator with zero findings. No checker import or main invocation occurred.

Corrected checker SHA-256: 7c70b0b9e4843efa19c7301cb1884229621a525812528ace70bf913eb4580de1

Interpretation and remaining gates

A canonical omission admitting the held x would obstruct membership alone under the stated visitation/traversal assumptions. Zero such witnesses would be necessary-condition compatibility only. Full fixed(x,y) predicates already determine b and cannot independently establish chronology. The broader 69-position census and the full commonality objective remain outside this finite necessary test.

Source commit and prospective freeze must precede data; lawful admission, approval, execution, export and independent review are still required. A 60-second runtime estimate is explicitly unmeasured. The separate process watchdog is prospective protection, not a scientific spending cap.

Sources and preserved failures

Primary: Anthropic, Claude reveals ECDSA curve origins (16 October 2026), its point recipe and open questions. Internal: prior point-first, base-point workflow and direct-stream reports, exact parameter records, protocol schema and validator. The bundled Python lacked jsonschema; native Python supplied it. A singular draft fixture was replaced before data. Coordination API/CLI timeouts stopped writes; the same task/epoch was re-confirmed before materialization. Exact details, hashes and original/corrected source are adjacent.
