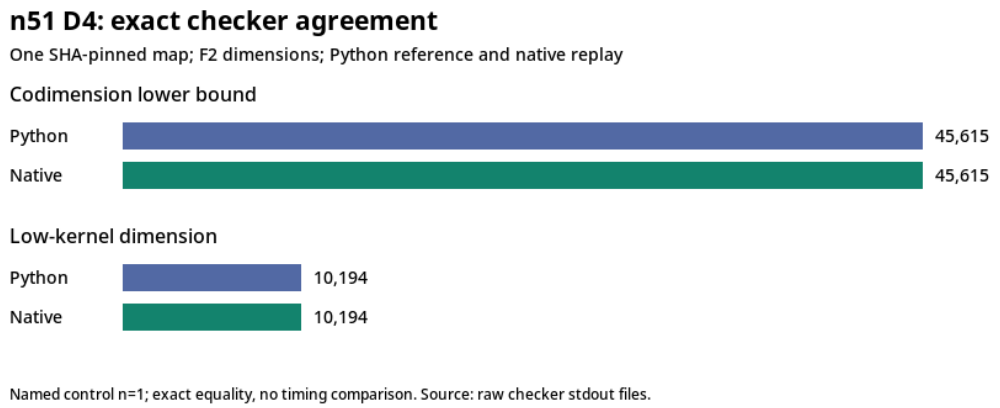
Independent native n51 degree-four checker control



The separately implemented native checker accepted the named affine-sliced D4 quotient map and all 51 variable-closure checks. Its exact dimension results matched the prior independent Python acceptance on the same certificate.

Check	Native	Python reference
Degree / variables / generators	4 / 51 / 51	4 / 51 / 51
Codimension lower bound	45,615	45,615
Low-kernel dimension	10,194	10,194
C0-C3 / exit	Accepted / 0	Accepted / 0

The map is 1,553,961,056 bytes, SHA-256 be38aff828d9d3c73e70ea78914727fdca1305edbf5f99e99b28aa747cc396d8. The independently exported 121,944-byte generator file has SHA-256 31bb28a3f45ca99ed169f3fcc850ef3c88a96157296161f15a6150543e8e0ec6. The checker hashes both before validation. Source, binary, protocol, command, receipts, and raw transcript hashes are bound in evidence.json.

One bounded native check used one CPU, a 12 GiB address-space cap, a 3,600-second timeout, and a USD 3 reservation. This qualifies the checker on the D4 control. Any D5 candidate requires a separate full-size independent check; this control alone does not raise an LFD bound.
