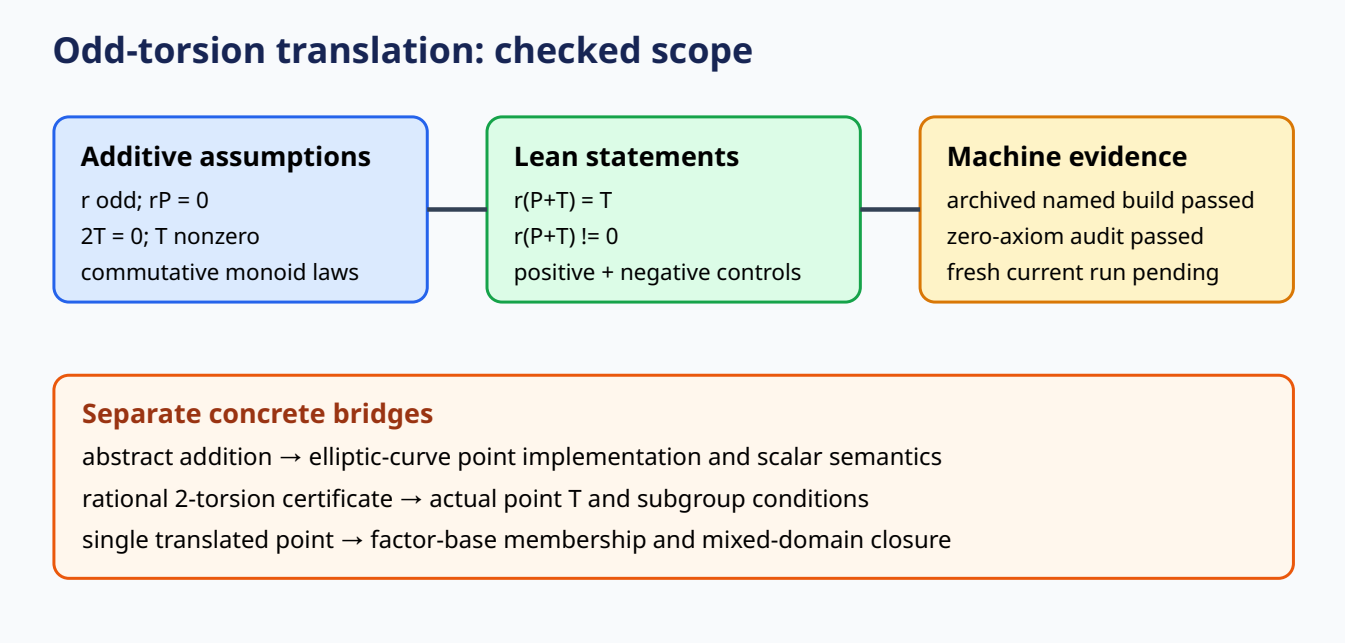
Odd-torsion translation proof review

2026-11-03

Checked component. Three independent joints support the abstract additive-law statement. A blind derivation gives $r(P+T)=T$ when r is odd, $rP=0$, and $2T=0$; $T\neq 0$ gives kernel exclusion. Explicit positive, even-scalar, and zero-T controls test the hypotheses.

Lean evidence. The archived named hosted run passed its Torsion module build and zero-axiom audit. The downloaded receipt matches the frozen SHA-256 and complete input maps. Eleven hostile receipt mutations were rejected. The fresh current-head formal job was still running at reviewer freeze; an independent binary/kernel recheck was not performed.

Verdict. Semantic fidelity is faithful for the conditional additive statement. The archived machine result holds at byte-identical source scope. Full current-head validation remains inconclusive until the fresh formal result is checked. Concrete curve, point arithmetic, torsion certificate, and factor-base bridges remain separate.



Exact hashes, independent reports, the local Lean timeout, the older receipt mismatch, and the attestation-format adapter are preserved in REVIEW.md and reviews/.
