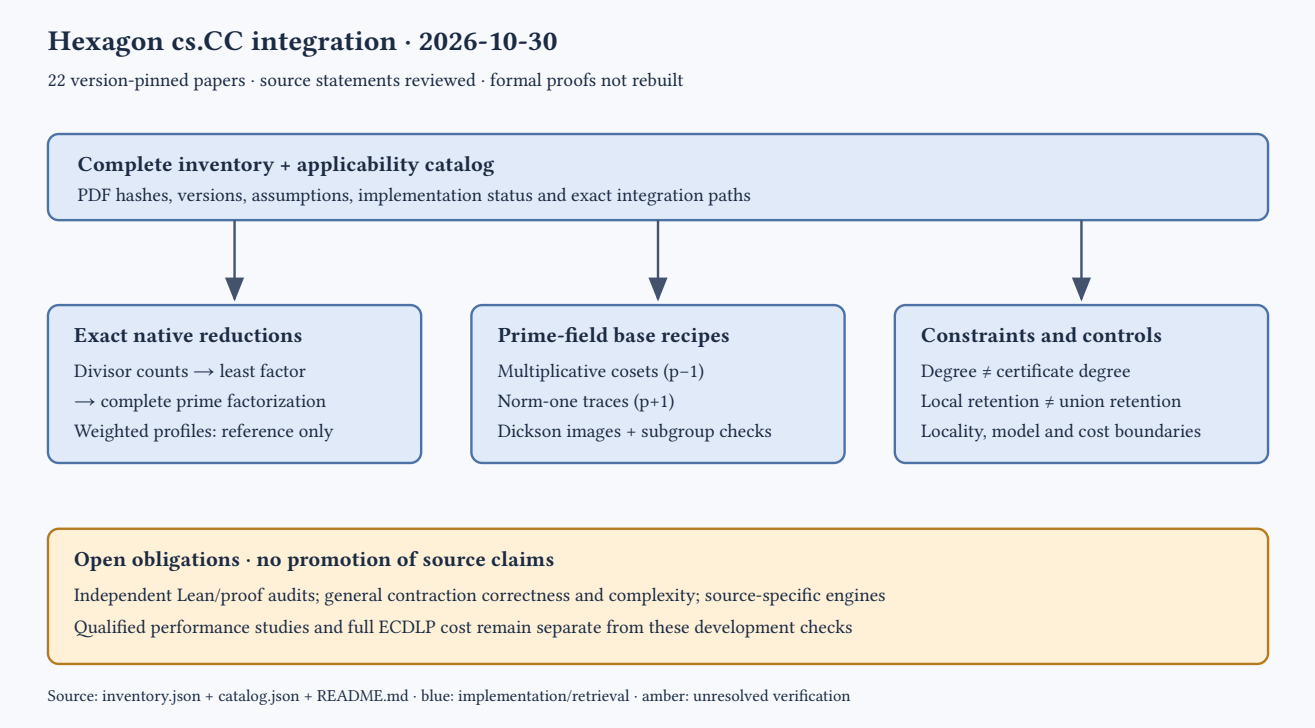
# Hexagon source intake — Crypto Autoresearcher

2026-10-30 · source curation and native integration pointers

The complete dated cs.CC snapshot contains 22 works. Their primary PDFs were retrieved and hashed, and source statements and relevant limits were reviewed. Twenty-two versioned literature notes retain those reported claims and their assumptions. A separate direct review of Petit–Kosters–Messeng, PKC 2016, sections 3.1–3.4, supersedes the earlier abstract-only PKM note KN-LIT-025. Knowledge-map.json identifies every new note; the source indexes are regenerated.



**Executable pointers.** The paired crypto change provides exact divisor-prefix factoring with the existing OpenAI-based counter, exhaustive weighted cost profiles, three structured prime-field factor-base recipes, a native searchable catalog and two finite counterexample controls. Cryptanalysis imports the new tensor modules. These are bounded software integrations; the source papers' asymptotic claims are not inherited by these implementations.

**Validation.** Sixteen source-index unit tests and both generated-index checks pass. The full ledger validator refuses the sparse checkout; its bypass was not used and full-corpus validation remains unpassed locally. The checked-in logs retain those exact outcomes. No hypothesis, finding, goal, disposition, frontier or attack-cost status is promoted, and there is no new performance data.

**Open work.** Complete proof audits and Lean builds, the general tensor correctness/complexity audit, the Anthropic engine port, subexponential weighted contraction and the fast Subset Sum/3SUM engines remain unperformed. The paired crypto report at research/hexagon_cscc_20261030/ contains all 22 source entries, their implementation status and the development verification record.
