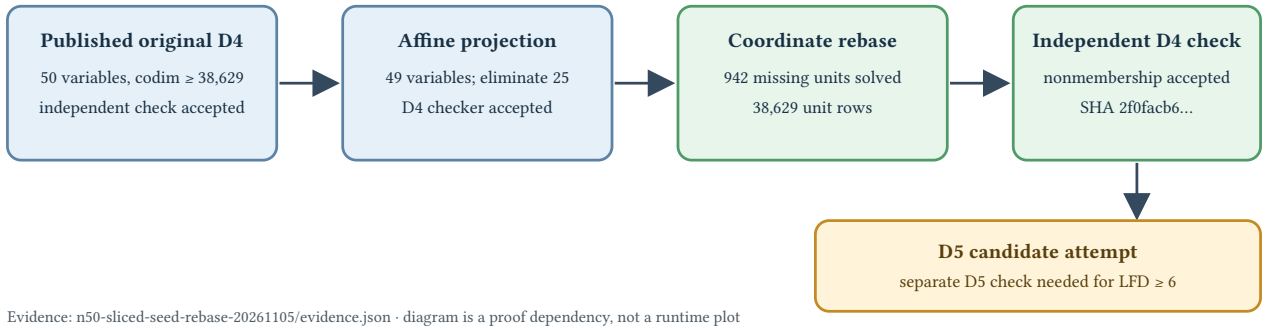
A checked 49-variable seed for the n50 degree-five search

The affine-sliced n50 polynomial03 quotient map has been rebased into the unit-triangular format required by the degree-five worker. The 1,120,585,872-byte output has SHA-256 `2f0facb6b047c857908e7f44e8558248af426dae10454263294df1a93d39cce8`. An independent checker accepted degree-4 nonmembership with codimension at least 38,629, including a nonzero image of 1.

n50 polynomial03: checked seed and degree-five gate



Evidence: n50-sliced-seed-rebase-20261105/evidence.json · diagram is a proof dependency, not a runtime plot

The published original certificate has raw SHA-256 `6a25ce310435e564b5487975c17de90f2903a401e8721d95781cf7049f688719`. The certified affine equation with combination mask `0x13c4f635ad45c` eliminates variable 25. Projection produced an independently accepted 49-variable degree-4 map. The projected map retained 37,687 literal unit coordinates and lacked 942; the accelerated rebase solved those 942 coordinates and the independent checker accepted the output again. The transfer statement is Proposition 2.5b of the theorem dossier.

Conversion records

Attempt	Terminal outcome	Wall time
Python full basis	Terminated; no output	1,337.1 s
Native full basis	One-hour timeout; no output	3,600.3 s
Native missing-coordinate	Output independently accepted	29.6 s

These attempts have different completion states and are not a matched speed comparison. The fast code matched the generic rebase on an exhaustive 11-row kernel fixture and a 73-coordinate multiword fixture. A wrong hash was refused. The migrated host's n6 checkpoint-free control reproduced its retained hash, emitted no checkpoints, and refused a bad seed hash.

The capacity profile gives 40,927 degree-five border coordinates and 79,556 working coordinates. Its bounded-export formula estimated 34,760,782,170 bytes; the running worker binary reported 35,385,141,521 bytes at admission. Both are below the frozen 36 GiB child cap. These figures are allocation bounds, not measured peak RSS. The degree-five result is recorded separately under protocol V2 and requires a separate checker before any LFD lower-bound claim.

The complete local file paths, byte counts, SHA-256 values, and process receipts are in `evidence.json`. The published original certificate and committed source provide a replay route for the rebased seed.
