n45 polynomial01 local admission refusal

The launcher exited 73 before starting the worker. Available memory was 35,684,368,384 bytes; the unchanged 40 GiB child cap plus 2 GiB reserve requires 45,097,156,608 bytes. Both campaign locks were acquired before the memory check. No child receipt, count, producer, checker or certificate exists for this attempt.

Zero scientific stages executed. The two-stage frozen protocol remains unfulfilled; no trial rows or successful export are fabricated. This is host admission evidence only, not a failure of the polynomial system or an upper/lower LFD bound. All nine original unfinished panel inputs remain in scope, including this input. The 40 unfinished original high-memory inputs remain unchanged.

The exact admission record and observed launcher exit are retained in validation/panel-local-n45-poly01-refusal-001. The frozen protocol hash is d3101090f23a2f02a712b2935032cba5e3a6fc49730efb3acaa726031e61f1a9. Concurrent compiler processes were observed on the shared host; they were not stopped or altered.

Next: recheck actual memory availability and ownership. A continuation requires sufficient headroom under the same cap, a new output identity and prospective frozen execution record. Preserve this refusal and do not overwrite or bypass the guard. The cloud n47 job remains independent.

> Available 35,684,368,384 bytes < required 45,097,156,608
>
> Memory admission refused ⟶ no worker started
>
> 0 scientific stages; original input remains unknown
