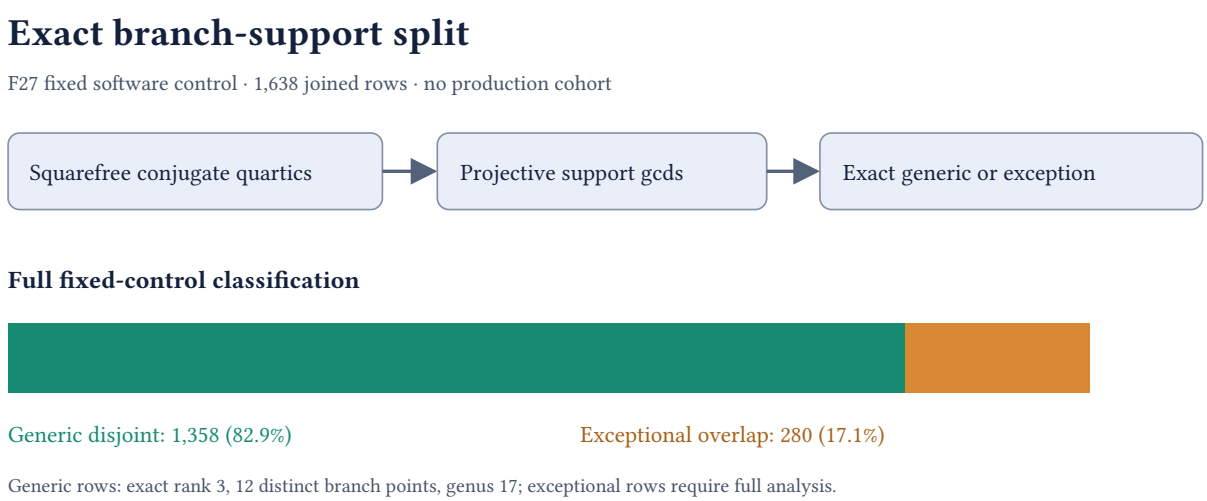
EXP-PEXT-bf8f96: generic branch-support certificate

The classifier checks that the binary quartics form a squarefree Frobenius orbit, then checks every pair for a finite common root and a shared point at infinity. If all supports are disjoint, every nonempty product has a unique simple branch point: both square-class ranks are n, the 2^n cover is connected, and its geometric genus is (n-1)2^n+1. Overlap cases retain their exact colliding pair and require full rank, genus and descent checks.



Fixed software control. On all 1,638 F27 join rows, 1,358 were generic disjoint and 280 had an overlap. For every generic row, the separate square-relation checker found only the zero relation; n=3 gives genus 17. Repeated-root and broken-conjugacy mutations were rejected. The figure is generated from `software-tests.json`; this is neither a production cohort nor a throughput measurement.

Next construction. Produce an exact, independently checked generator of all exceptional structure indices. Only its proven complement may receive the generic geometric count without visiting every position. P1-P4, H1, twists, descent and Type2 remain in the full contract. The experiment is review_required; no scientific trial ran.
