Original tables and binary compatibility

28 October 2026 UTC | T-5518 | table-artifacts-01

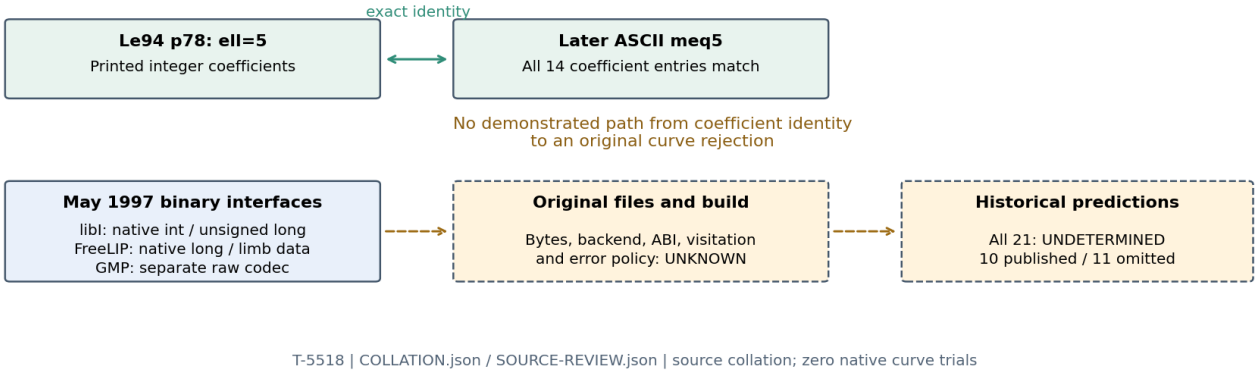

Historical selector unresolved. This source-only round verifies a dated polynomial coefficient witness, reads the binary interfaces preserved in May 1997 and checks an archived history lead. It runs no original point counter and no new scientific trial.

Dated coefficient identity. Lehmann's 1994 thesis, printed p78 / PDF p79, gives the complete ell=5 polynomial:

```
G5(X,J) = (X^2+10X+5)^3 - J*X
```

All seven rows / 14 coefficient entries match the later ASCII meq5 file exactly. The printed modulo 101 table agrees with reduction of those integers. A separate convolution verifies the polynomial identity. The original source page was visually inspected, including the negative J coefficient.

A real compatibility dependency; original execution remains unknown

T-5518 | COLLATION.json / SOURCE-REVIEW.json | source collation; zero native curve trials

Printed index inconsistency. An intermediate boxed a_0,0=43 conflicts with the final a_0,0=24 modulo 101. Its surrounding calculation concerns a_1,0=43; both final tables agree with the coefficient identity. This is not evidence of a native program defect.

All 21 identities retained. The crosswalk checks each p,b,n,seed,ordinal and full UID against the frozen prior rows and verifies the imported CSV against its original archive seal. Historical table bytes, backend/ABI, level visitation and error policy remain UNKNOWN for every curve. Therefore all ten publication and eleven omission predictions under the I/O explanation are UNDETERMINED.

The ell=5 identity establishes one mathematical table witness. It authenticates neither the original binary bytes nor use by NIST. Existing P-224 cube/splitting and ell 199 separator observations retain their earlier limits. No new conductor, endomorphism or transfer conclusion follows.

What the actual I/O source requires

The preserved May 1997 package has backend-specific binary interfaces. None of these source observations identifies an omission-specific consequence without original files and caller behavior.

Backend	Binary interface observed
libI	Three native int fields, then length native unsigned-long digits. Endianness, widths and representation matter.
FreeLIP	Native long words, including signed digit count and limb payload. The LiDIA wrapper discards the lower-level read-status return.
GMP	mpz_out_raw / mpz_inp_raw. Its header records a binary/text API-body exchange on 9 January 1997; pre-change bodies are not recovered.

Later reader boundary. The later 2.3.0 meq reader prefers ASCII, then binary/compressed forms; binary rows call its selected bigint backend. Its modulus-taking reader handles compressed inputs during polynomial construction. The canonical private copy matches Git blob 01bec36819fde2ea247872e6add0ed578fe3bdbb. It is not authenticated 1997 source.

Archive lead resolved. The Software Heritage LiDIA-history snapshot returns an empty branch map and no next page. Earlier full-visit metadata does not mean historical code was preserved there. The GitHub repository advertises size 0. This closes that specific lead, not all possible CVS/SVN archives.

Access limits. The 1999/2000 project-page captures describe the counter as outside the free distribution. One filtered CDX query is empty and three prefix queries time out; no absence proof follows. Original atobin/bintoa bodies, actual table files, binary build and caller remain missing.

Verification and custody. Coefficient collation, all 21 input bindings and the public seal pass. Fresh-directory metadata replay verifies 16 sealed members and the coefficient identities without native execution or network. Raw commit dda4dd955f was pushed first. The 16,808-byte archive excludes original code/package/HTML/PDF bodies. The initial archival file-count assertion stopped before committing, then the inspected 22-file set was committed.

Next discriminating evidence. Recover an actual standalone ECO distribution or original caller/table set. Freeze any precise recovered mechanism before an untuned comparison of all eleven omissions and ten publications. The overall goal stays active.
