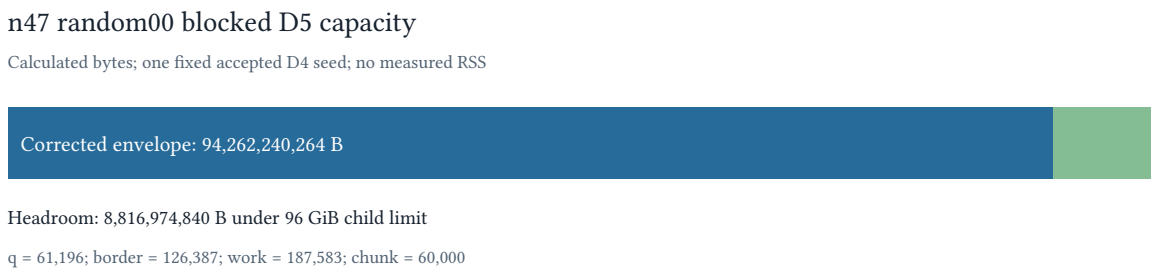
n47 random00 D5 capacity after the interrupted attempt

The accepted n47 random00 D4 seed has 61,196 quotient coordinates. Two independent border enumerations agree on 126,387 more, giving 187,583 D5 working coordinates. At chunk 60,000 the bounded-export base payload is 68,185,663,280 bytes. No D5 closure was run in this profile.

The blocked source adds 1,588,508,128 bytes of padded workspace. Its integer 135/100 margin and 64 MiB reserve give a corrected envelope of **94,262,240,264 bytes**, leaving **8,816,974,840 bytes** below the 96 GiB child limit. These are source-derived bytes, not observed RSS or host admission.



The earlier random00 D5 attempt freshly counted zero solutions and rechecked the D4 seed, but its Spot node shut down before any D5 certificate or native checkpoint. Evidence: reports/seed-reuse-frontier-interruption-001 and validation/rand00-envelope-001/result.json. A future blocked attempt needs a frozen request, runtime admission, and independent D5 checking. Any accepted positive D5 codimension would prove LFD at least six for this named input. Random02 and random03 retain their current execution order.
