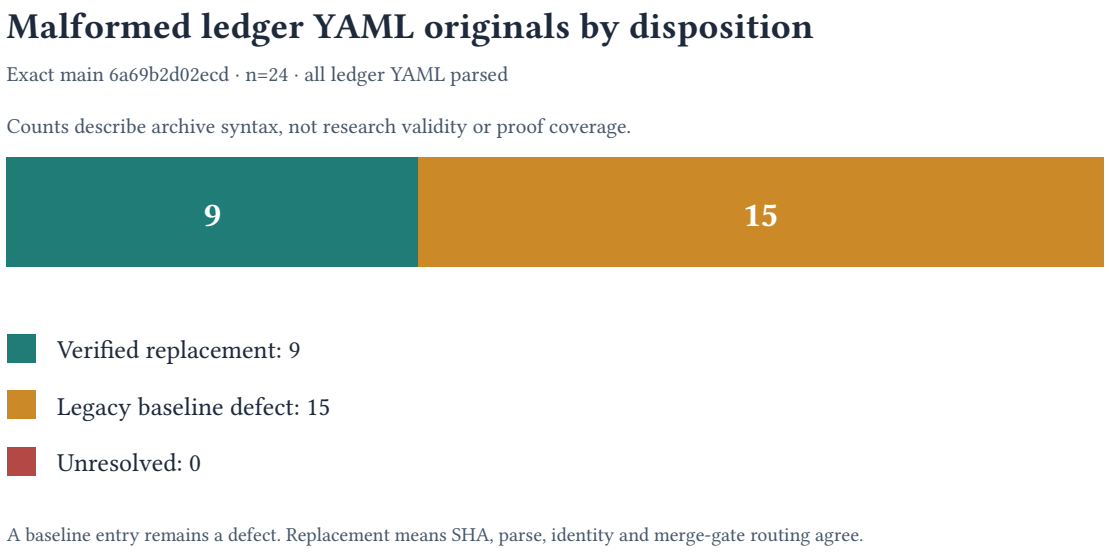
Ledger YAML parse disposition audit

26 October 2026 · crypto-autoresearcher main `6a69b2d02ecd53f1649bcf56e23e4ffe91d953ad`

This is a read-only syntax and archive-routing audit. It makes no cryptographic performance or proof-completeness claim.

Question and source

The exact-main static dashboard reports 24 unparseable ledger YAML originals. `audit.py` parses every `ledger/**/*.yaml` file, verifies registered original and replacement SHA-256 pins, parses each replacement, checks its record ID, cross-checks the merge gate, and compares the legacy baseline. The complete per-path result is `evidence.json`; `render.py` produces the chart below.



Observation and meaning

Disposition	Count	Meaning
Verified schema replacement	9	Archived malformed original with hash-bound, parseable, same-ID copy; semantic fidelity still needs review.
Legacy parse baseline	15	Disclosed syntax defect with no verified replacement in this audit.
Other unresolved	0	No further malformed ledger YAML in this exact-main sweep.

The original records remain immutable. The 15 baseline entries remain defects; the repository's merge gate allows them only as disclosed historical debt. Neither the chart nor a parseable replacement verifies the research statement.

Exit check

For each baseline record, preserve the original, add a semantically reviewed parseable schema copy, pin both hashes, remove its baseline line, and rerun the absolute merge-hygiene gate, ledger validator and this audit. Success requires the baseline count to fall without creating an unresolved failure. The full experiment and Lean proof validation remains separate.
