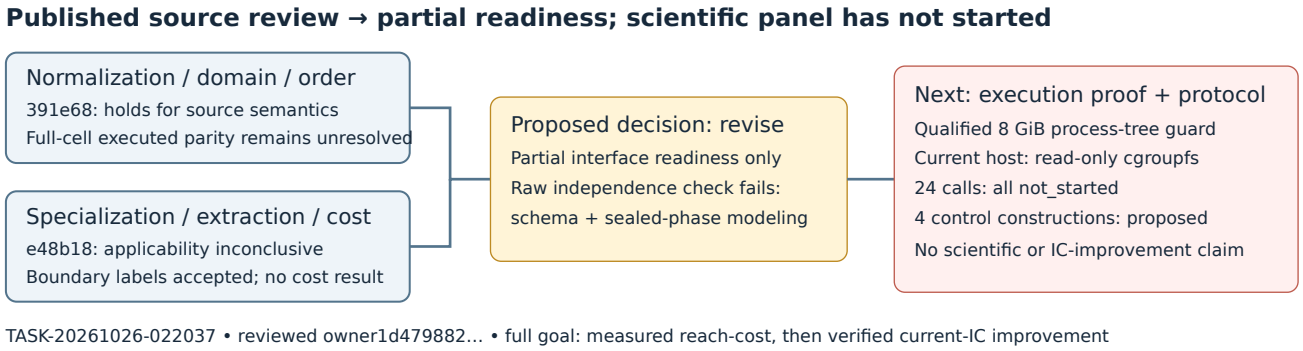
Native joint-smallroot review composition

TASK-20261026-022037 · BATCH-ee839d · 26 October 2026

Proposed DEC-20261026-cf272f: revise; partial interface readiness only. No official DEC, experiment approval, scientific state transition or IC improvement is recorded. The original goal remains a measured joint-system reach-cost tradeoff, then verified improvement over the named frozen current prime-field IC baseline.



Observation and source custody

Producer ten-output archive: 0baa7b0901230b23dce945adc55695abd3e48249. Reviewed published owner source: crypto commit 1d47988261c4d13f7a8549d70f53571163246c77, PR 2642. Normalization reviewer checked seven relevant source blobs; specialization reviewer checked all 77 manifest paths. Exact source records and two genuine independent reports support source custody, not executed scientific equivalence.

No scientific call occurred. All24 symbolic cells remain not_started; scientific metrics are null. Reduction and extraction are not_requested. Four D-sign ideal/domain/closure constructions remain a separate proposed, unapproved control amendment.

The later integrated owner library log records 4862 passed, 0 failed, 121 ignored in 1217.09 s. Its final result was inspected. It is software validation, not scientific cell execution or a claim that every integrated revision was reviewed. Earlier 4844/18 missing-fixture failures and 18 passing same-binary rechecks remain preserved. Owner branch reconciliation/publication is handled by parent; the immutable reviewed source remains the evidence anchor.

Comparison of owned joints

Owned joint	Actual conclusion and boundary
391e68: normalization, domain, order	Holds for published-source semantics: affine equations, six/seven coordinates, weighted order, convex integer domain, one multiplicity normalization and constant-pivot intersection agree with sealed derivation. UNRESOLVED-NDO-1: full-cell domain/intersection executed parity is absent.
e48b18: specialization, extraction, cost	Inconclusive for applicability/readiness; source boundary labels accepted. Finite specialization, denominator/leading coefficient/pivot and ideal/span preservation, extractable equations, group recovery and full charged cost remain unresolved.

These are distinct joints, not votes. For $a=2,b=3,275=5^2\cdot11$ excludes singular finite specializations p=5, 11. X-only zeros do not select signed group relations. $S(1,3,41)=4545=45\cdot101$, while support-preserving F1+1 is 1 modulo 101. These hand/source counterexamples constrain interpretation; no supervised control ran.

Inference, procedure and next action

Primary source and remaining assumptions

Both independent reviewers retrieved/read the 52-page Ryan primary paper: ePrint 2024/1577, archived capture 20250716082047, SHA256 15dd6ae6b939c51f3bc124097f954bd858ef47e4739037381fb4951f0366043f. I verified the PDF hash and inspected primary text for Heuristics 1/2 and Lemma 7. This resolves the earlier access/read gap, not applicability. Lemma 7 assumes shared-root/suitability obligations, its heuristics, proportional specialization, sufficiently large p, a strict bound and the stated log-p growth; its polynomial-time statement excludes final root recovery.

Independence: actual failure retained

The real check_review_independence.py command exits1 with two problems. Specialization uses joint_owned instead of required joints_owned. Normalization's all-phase read list includes producer files deliberately opened after its sealed derivation; the flat checker applies blind_from to that combined list. The raw output and exact input hashes are preserved in independence-check.json. No mechanical pass is asserted.

Both reports attest no sibling report reads. Recomputed derivation/seal hashes match; seal time is 2026-10-26T19:19:50Z and notification before implementation access is recorded. A separate declared pre-seal filename-only glob exposed path names, with no technical content declared read. All three procedure issues are explicit; no reviewer file, frozen plan or attestation was rewritten. These declarations support qualified phase-aware source assessment, not a perfect independence gate, theorem approval or experiment approval.

One next action

Executor-implementation: complete actual source execution-proof and a guard-qualified protocol before the 24-call panel. Bind exact source/intermediates, address failure semantics and authoritative upstream-receipt interpretation, and retain the control amendment separately until adopted. Current read-only cgroupfs cannot enforce the required 8589934592-byte process-tree guard; approval bounded by execution cannot pass here. Compatible host information is pending separately; standing research authorization is already satisfied. No unguarded substitute is authorized.

Exact-byte approvable:true preapproval, Director/runbook/card gates, published approval/readiness and lawful live ownership remain later requirements. Whole-call cgroup CPU/memory is planned; per-phase worker CPU excludes children and cannot be sold as complete phase cost. No attack-cost observation exists.

Full success remains unresolved: verified decomposition/DLP, current-IC baseline and identical instances/resources, every phase and failed attempt charged, matched rho gap, independent replay and progress-fidelity evidence. Knowledge promotion:none; no new scientific finding. Canonical reach-cost.svg, review-20261024/accounting.svg and readiness-20261025/weighted-reach.svg stay unchanged because no scientific quantity or edge changed. The diagram is review coverage/gates, not a quantitative results graph.
